

DATA SCIENCE TOOLS, PART 2: PANDAS, MATPLOTLIB

Pandas

matplotlib

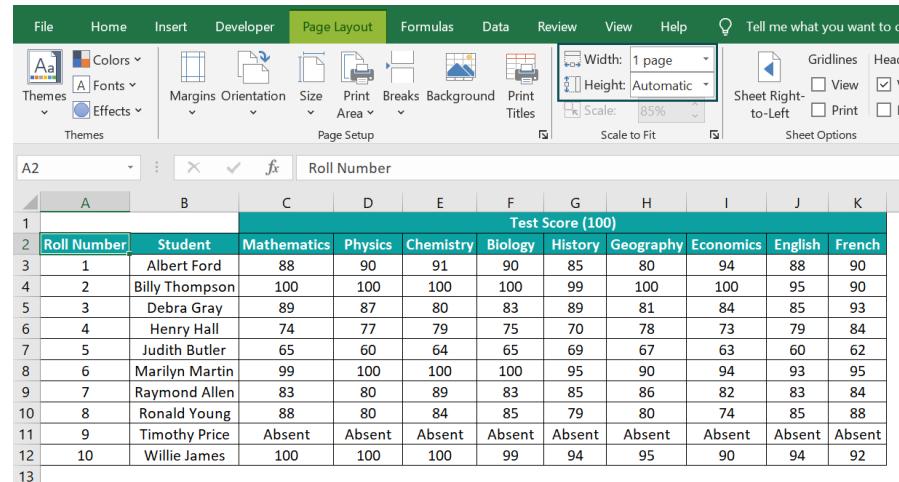

PRE-QUIZ: HOW MUCH DO YOU ALREADY KNOW ABOUT PANDAS?

- What is python pandas?
- How is a pandas DataFrame different than a NumPy array?
- Name three unique operations (i.e., methods) you can do with pandas?
- How do you read from or write to a csv file using pandas?
- Keep this Quiz and see if you can fill-in any missing questions during the discussion today

WHAT IS PANDAS?

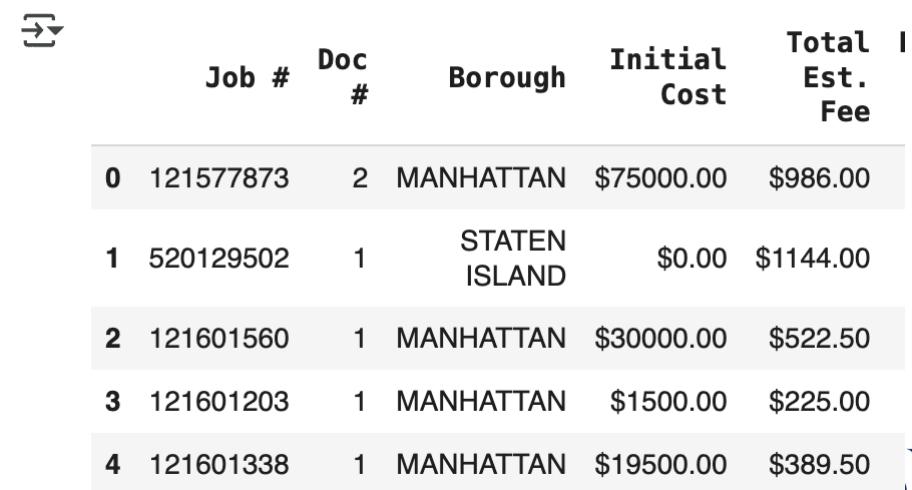

- Think of pandas as Excel for Python.
- If you've ever used **Excel** or **Google Sheets** – adding columns, filtering rows, making summaries – pandas does the same, but with code.

A screenshot of Microsoft Excel showing a table of student test scores. The table has 13 columns: Roll Number, Student, Mathematics, Physics, Chemistry, Biology, History, Geography, Economics, English, and French. The first two rows are headers, and there are 10 data rows from row 3 to row 12. Row 13 is a blank header row. The table is titled "Test Score (100)".

Test Score (100)												
	Roll Number	Student	Mathematics	Physics	Chemistry	Biology	History	Geography	Economics	English	French	
3	1	Albert Ford	88	90	91	90	85	80	94	88	90	
4	2	Billy Thompson	100	100	100	100	99	100	100	95	90	
5	3	Debra Gray	89	87	80	83	89	81	84	85	93	
6	4	Henry Hall	74	77	79	75	70	78	73	79	84	
7	5	Judith Butler	65	60	64	65	69	67	63	60	62	
8	6	Marilyn Martin	99	100	100	100	95	90	94	93	95	
9	7	Raymond Allen	83	80	89	83	85	86	82	83	84	
10	8	Ronald Young	88	80	84	85	79	80	74	85	88	
11	9	Timothy Price	Absent	Absent	Absent	Absent	Absent	Absent	Absent	Absent	Absent	
12	10	Willie James	100	100	100	99	94	95	90	94	92	
13												

`df.head()`

A screenshot of a Jupyter Notebook cell showing the output of the `df.head()` command. The output displays the first five rows of a DataFrame. The columns are Job #, Doc #, Borough, Initial Cost, and Total Est. Fee. The data shows various job entries with their respective details.

	Job #	Doc #	Borough	Initial Cost	Total Est. Fee
0	121577873	2	MANHATTAN	\$75000.00	\$986.00
1	520129502	1	STATEN ISLAND	\$0.00	\$1144.00
2	121601560	1	MANHATTAN	\$30000.00	\$522.50
3	121601203	1	MANHATTAN	\$1500.00	\$225.00
4	121601338	1	MANHATTAN	\$19500.00	\$389.50

PANDAS DEFINITION

- Open-Source software library written for Python
- Pandas derived from the term “**panel data**” from econometrics
- Data structures and operations for manipulating numerical tables and time series
- DataFrame is a 2-Dimensional structure built as a combination of Series arrays with a shared index
- Built on NumPy
- Originally released 11 Jan 2008. The current stable release is **version 2.3.2**, released August 21, 2025.

[https://en.wikipedia.org/wiki/Pandas_\(software\)](https://en.wikipedia.org/wiki/Pandas_(software))

BYU

PANDAS SERIES

A **pandas Series** is a one-dimensional labeled array, capable of holding data of any type (integers, floats, strings, Python objects, etc.).

Key features of a pandas Series:

- **Indexing:** Each element in the Series has a corresponding index, which allows for easy access and manipulation of data. Default is numeric indexing.
- **Homogeneous:** The Series can hold elements of the same type (though mixed types are possible, but uncommon and not recommended practice).

python

```
import pandas as pd

# Create a pandas Series
data = pd.Series([10, 20, 30, 40], index=['a', 'b', 'c', 'd'])

print(data)
```

This will output:

```
a    10
b    20
c    30
d    40
dtype: int64
```

PANDAS DATAFRAME

- Defined as multiple **Series** objects that share an index
- A **Pandas DataFrame** is a two-dimensional, labeled data structure in Python, similar to a table or spreadsheet, that stores data in rows and columns. Each column in a DataFrame can have a different data type (e.g., integers, floats, strings, etc.).

Key features of a DataFrame:

- Rows and Columns:** Like a table, with rows representing individual records and columns representing variables or features.
- Labels:** Rows and columns can have labels (names), making it easy to access, slice, or manipulate data. Index and Column for row/column labels
- Data Handling:** It can handle missing data and supports arithmetic operations, data filtering, aggregation, and transformation.
- Data Input/Output:** Can read and write data from various file formats (e.g., CSV, Excel, SQL, etc.).

Example:

```
python
import pandas as pd

# Create a DataFrame
data = {
    'Name': ['Alice', 'Bob', 'Charlie'],
    'Age': [25, 30, 35],
    'City': ['New York', 'San Francisco', 'Los Angeles']
}

df = pd.DataFrame(data)

print(df)
```

This code would output:

	Name	Age	City
0	Alice	25	New York
1	Bob	30	San Francisco
2	Charlie	35	Los Angeles

SUBSETTING DATA

- *Subsetting data* involves choosing specific rows and columns from a dataframe according to labels, indices, and slices.
- A single column can be selected by using the label of the desired column. Ex: Using the country dataset assigned to the variable country, the Population column can be selected using the country['Population'] or country.Population. Multiple columns can also be selected by using an array of strings. Ex: country[['Name', 'Population']]
- The iloc(x,y) method for a dataframe is used to select an individual element using an index location, where x is the row and y is the column. Ex: country.iloc[0,1] returns the element in row 0 and column 1. The colon character : is used in slice notation to select multiple rows or columns. Ex: country.iloc[:5,1:3] returns rows before row 5 and columns 1 thru 2.
- The loc(x,y) method can also be used to subset data, but y, in this case, is an array of column labels, instead of an integer or a range of integers. Ex:
Both country.iloc[:7,1:3] and country.loc[:6,['Continent','Population']] give the same results.

CONDITIONAL FILTERING

- Comparison and logical operators can be used to subset data. When these operators are used, only rows for which the expression is true will be returned. Ex: `country[country['Population'] > 100000]` will display rows whose 'Population' column values are greater than 100,000.

MISSING VALUES

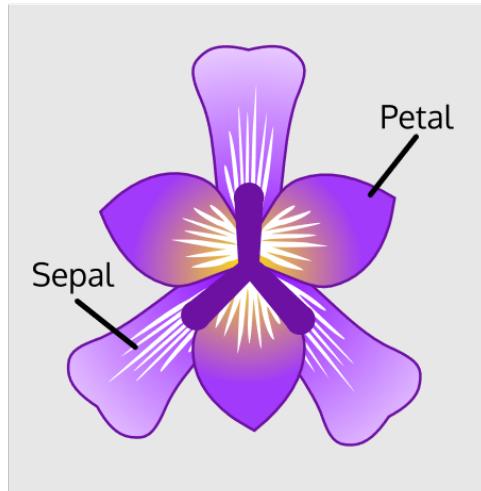

There are several methods to deal with missing values in the data frame:

df.method()	description
dropna()	Drop missing observations
dropna(how='all')	Drop observations where all cells is NA
dropna(axis=1, how='all')	Drop column if all the values are missing
dropna(thresh = 5)	Drop rows that contain less than 5 non-missing values
fillna(0)	Replace missing values with zeros
isnull()	returns True if the value is missing
notnull()	Returns True for non-missing values

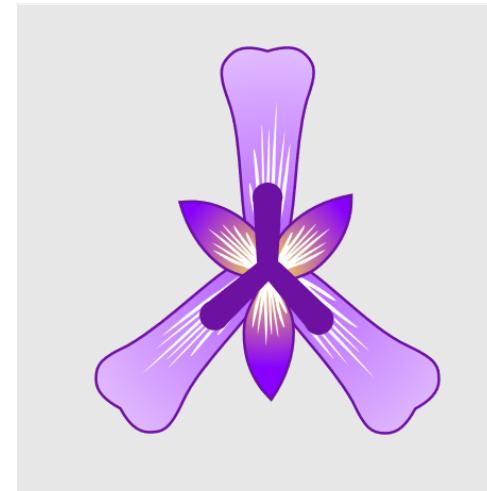

IRIS FLOWER DATA SET

- The **Iris flower data set** was made famous by the British statistician and biologist Ronald Fisher in 1936.
- It is sometimes called Anderson's Iris data set because Edgar Anderson collected the data to quantify the morphologic variation of Iris flowers of three related species.
- The dataset contains a set of 150 records with five attributes: sepal length, sepal width, petal length, petal width and species.
- The iris data set is widely used for teaching machine learning. The dataset is included in Python in the machine learning library [scikit-learn](#).

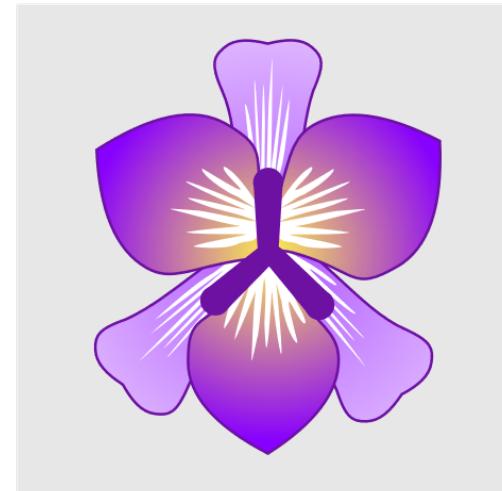

https://en.wikipedia.org/wiki/Iris_flower_data_set#External_links

Iris Versicolor

Iris Setosa

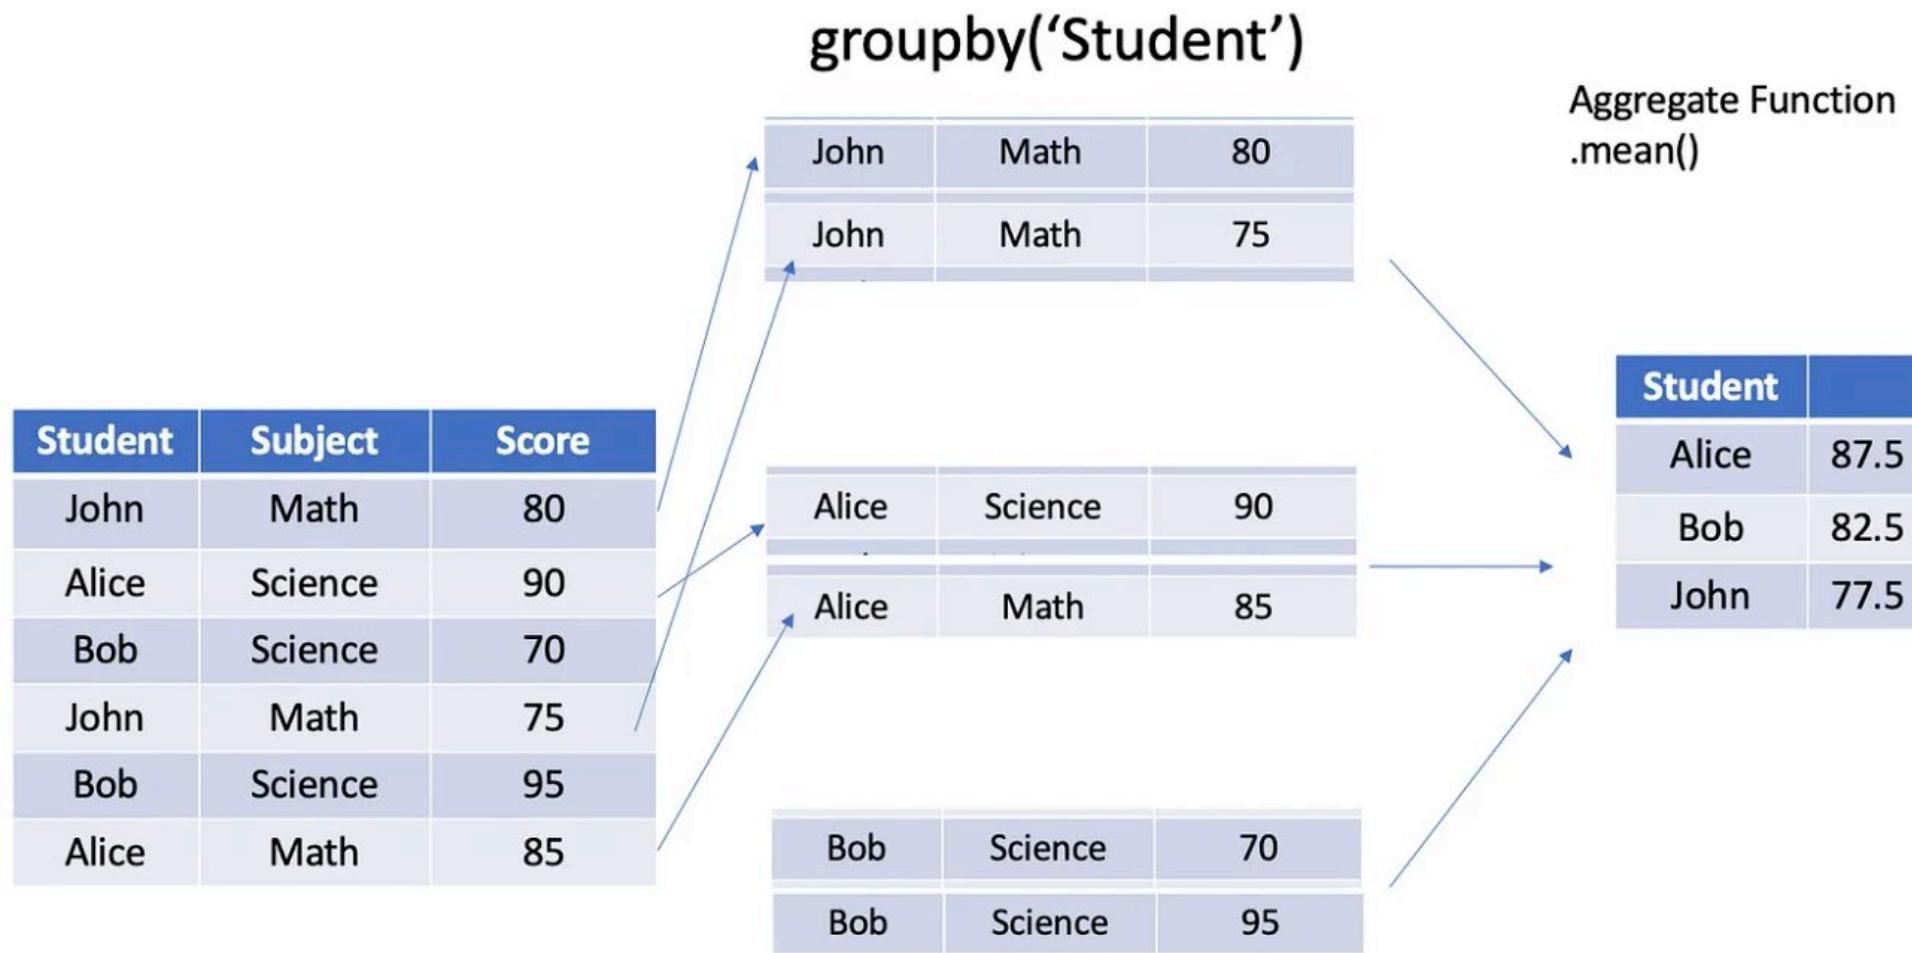

Iris Virginica

```
from sklearn.datasets import load_iris  
  
iris = load_iris()  
iris
```

This code gives:

```
{'data': array([[5.1, 3.5, 1.4, 0.2],  
               [4.9, 3., 1.4, 0.2],  
               [4.7, 3.2, 1.3, 0.2],  
               [4.6, 3.1, 1.5, 0.2],...  
              'target': array([0, 0, 0, ... 1, 1, 1, ... 2, 2, 2, ...  
              'target_names': array(['setosa', 'versicolor', 'virginica'],  
              dtype='<U10'),  
              ...}
```

GROUPBY GENERAL CONCEPT

BYU

QUIZ: HOW MUCH DO YOU NOW KNOW ABOUT PANDAS?

- What is Python Pandas?
- How is a Pandas DataFrame different than a NumPy array?
- Name three unique operations (i.e., methods) you can do with Pandas?
- How do you read from or write to a csv file using Pandas?

MATPLOTLIB

Matplotlib is a popular Python library used for creating static, animated, and interactive visualizations. Matplotlib can produce a variety of plots, such as:

- Line plots
- Bar charts
- Scatter plots
- Histograms
- Pie charts
- 3D plots

It works closely with other libraries like NumPy for numerical computations and Pandas for handling data structures.

SEABORN

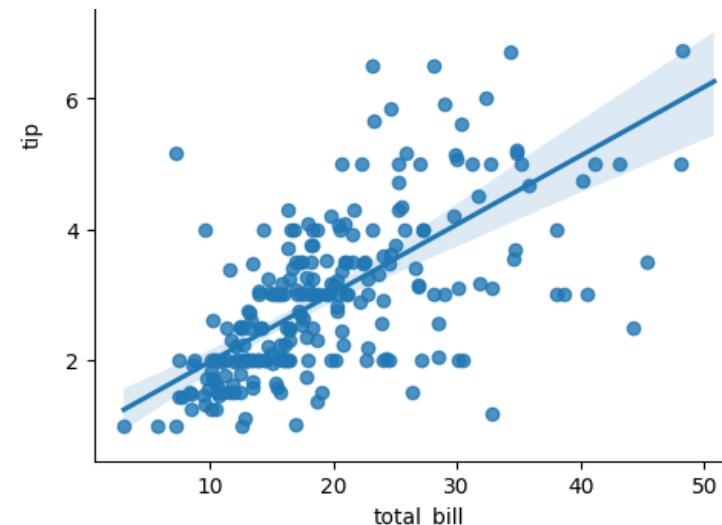

- Seaborn is a Python data visualization library built on top of Matplotlib, designed to make it easier to create informative and aesthetically pleasing statistical graphics.
- Seaborn integrates closely with Pandas data structures, which makes it especially powerful for working with data frames and structured data.
- **Plot Types:** Seaborn supports many types of plots, such as:
 - Line plots
 - Bar plots
 - Scatter plots
 - Heatmaps
 - **Pair plots (My favorite!)**
 - Box plots
 - Violin plots

```
import seaborn as sns
import matplotlib.pyplot as plt

# Load an example dataset from Seaborn
tips = sns.load_dataset("tips")

# Create a scatter plot with a linear fit
sns.lmplot(x="total_bill", y="tip", data=tips)

# Display the plot
plt.show()
```

BOX AND WHISKER PLOT

A **boxplot** is a standardized way of displaying the distribution of data based on a five-number summary: minimum, first quartile (Q1), median, third quartile (Q3), and maximum. It helps to show the spread and skewness of the data, highlighting potential outliers.

- **Key Elements :**
- 1. **Box:** Spans from Q1 to Q3 (the interquartile range, IQR).
- 2. **Median:** A line inside the box showing the middle of the dataset.
- 3. **Whiskers:** Lines extending from Q1 to the minimum and Q3 to the maximum values within 1.5 times the IQR.
- 4. **Outliers:** Data points that fall outside the whiskers.

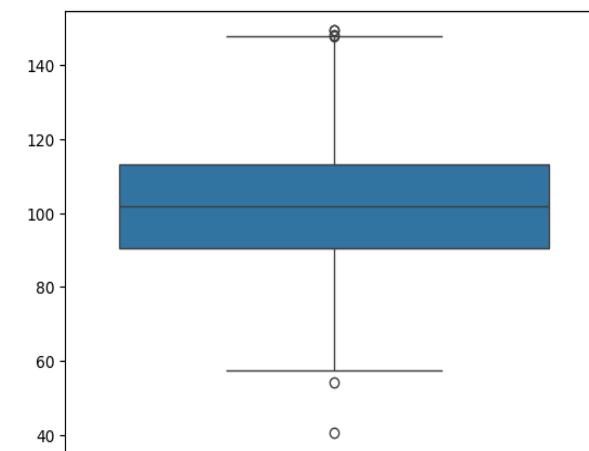

By combining these elements, a box plot quickly provides insights into the data's **distribution, variability, and any unusual observations** (like outliers).

```
import matplotlib.pyplot as plt
import seaborn as sns
import numpy as np

# Generate random data
np.random.seed(10)
data = np.random.normal(100, 20, 200)

# Create a boxplot using seaborn
sns.boxplot(data=data)

# Display the plot
plt.show()
```

APPENDIX

MOST COMMONLY USED PANDAS OPERATIONS

Data Wrangling
with pandas Cheat Sheet
<http://pandas.pydata.org>

Pandas API Reference Pandas User Guide

Creating DataFrames

```
df = pd.DataFrame({
    "a": [4, 5, 6],
    "b": [7, 8, 9],
    "c": [10, 11, 12],
    index=[1, 2, 3])
Specify values for each column.

df = pd.DataFrame([
    [4, 7, 10],
    [5, 8, 11],
    [6, 9, 12]],
    index=[1, 2, 3],
    columns=['a', 'b', 'c'])
Specify values for each row.
```

	a	b	c
1	4	7	10
2	5	8	11
3	6	9	12

df = pd.DataFrame(
 {"a": [4, 5, 6],
 "b": [7, 8, 9],
 "c": [10, 11, 12]},
 index=pd.MultiIndex.from_tuples(
 [('d', 1), ('d', 2),
 ('e', 2)], names=['n', 'v']))
Create DataFrame with a MultiIndex

Method Chaining

Most pandas methods return a DataFrame so that another pandas method can be applied to the result. This improves readability of code.

```
df = (pd.melt(df)
      .rename(columns={
          'variable': 'var',
          'value': 'val'})
      .query('val >= 200'))
```

Logic in Python (and pandas)

<	Less than	!=	Not equal to
>	Greater than	df.column.isin(values)	Group membership
==	Equal	pd.isnull(obj)	Is NaN
!=	Less than or equal	pd.notnull(obj)	Is not NaN
>=	Greater than or equal	&, , ~, &, df.any(), df.all()	Logical and, or, not, xor, any, all

Cheatsheet for pandas (<http://pandas.pydata.org>) originally written by Iv Lusic, Princeton Consultants, inspired by [Rstudio Data Wrangling CheatSheet](#)

Tidy Data – A foundation for wrangling in pandas

In a tidy data set:
 Each variable is saved in its own column
 Each observation is saved in its own row

Reshaping Data – Change layout, sorting, reindexing, renaming

pd.melt(df)
Gather columns into rows.
pd.pivot(columns='var', values='val')
Spread rows into columns.
pd.concat([df1, df2])
Append rows of DataFrames
pd.concat([df1, df2], axis=1)
Append columns of DataFrames

df.sort_values('mpg')
Orders rows by values of a column (low to high).
df.sort_values('mpg', ascending=False)
Orders rows by values of a column (high to low).
df.rename(columns = {'y': 'year'})
Rename the columns of a DataFrame
df.sort_index()
Sort the index of a DataFrame
df.reset_index()
Reset index of DataFrame to row numbers, moving index to columns.
df.drop(columns=['Length', 'Height'])
Drop columns from DataFrame

Subset Observations - rows

df[df.Length > 7]
Extract rows that meet logical criteria.
df.drop_duplicates()
Remove duplicate rows (only considers columns).
df.sample(frac=0.5)
Randomly select fraction of rows.
df.nlargest(n, 'value')
Select and order top n entries.
df.nsmallest(n, 'value')
Select and order bottom n entries.
df.head(n)
Select first n rows.
df.tail(n)
Select last n rows.

Subset Variables - columns

df[['width', 'length', 'species']]
Select multiple columns with specific names.
df['width'] or df.width
Select single column with specific name.
df.filter(regex='regEx')
Select columns whose name matches regular expression regex.

Using query

query() allows Boolean expressions for filtering rows.
df.query("Length > 7")
df.query("Length > 7 and Width < 8")
df.query("Name.str.startswith('abc')", engine="python")

regex (Regular Expressions) Examples

'.'	Matches strings containing a period ''
'Length\$'	Matches strings ending with word 'Length'
'*Sepal'	Matches strings beginning with the word 'Sepal'
'*[1-5]'	Matches strings beginning with 'x' and ending with 1,2,3,4,5
'^(?i:Species).*'	Matches strings except the string 'Species'

Summarize Data

df['w'].value_counts()
Count number of rows with each unique value of variable
len(df)
of rows in DataFrame.
df.shape
Tuple of # of rows, # of columns in DataFrame.

df['w'].unique()
of distinct values in a column.

df.describe()
Basic descriptive and statistics for each column (or GroupBy).

pandas provides a large set of **summary functions** that operate on different kinds of pandas objects (DataFrame columns, Series, GroupBy, Expanding and Rolling (see below)) and produce single values for each of the groups. When applied to a DataFrame, the result is returned as a pandas Series for each column. Examples:
sum()
Sum values of each object.
count()
Count non-NA/null values of each object.
median()
Median value of each object.
quantile([0.25, 0.75])
Quantiles of each object.
apply(function)
Apply function to each object.

Group Data

df.groupby(by='col')
Return a GroupBy object, grouped by values in column named "col".
df.groupby(level='ind')
Return a GroupBy object, grouped by values in index level named "ind".

All of the summary functions listed above can be applied to a group. Additional GroupBy functions:

Windows

df.expanding()
Return an Expanding object allowing summary functions to be applied cumulatively.
df.rolling(n)
Return a Rolling object allowing summary functions to be

Handling Missing Data

df.dropna()
Drop rows with any column having NA/null data.
df.fillna(value)
Replace all NA/null data with value.

Make New Columns

df.assign(Area=lambda df: df.Length*df.Height)
Compute and append one or more new columns.
df['volume'] = df.Length*df.Height*df.Depth
Add single column.
pd.qcut(df.col, n, labels=False)
Bin column into n buckets.

Combine Data Sets

Standard Joins

x1	x2	x3
A	1	T
B	2	F
C	3	NaN

pd.merge(adf, bdf,
how='left', on='x1')
Join matching rows from bdf to adf.

x1	x2	x3
A	1.0	T
B	2.0	F
D	NaN	T

pd.merge(adf, bdf,
how='right', on='x1')
Join matching rows from adf to bdf.

x1	x2	x3
A	1	F
B	2	F

pd.merge(adf, bdf,
how='inner', on='x1')
Join data. Retain only rows in both sets.

x1	x2	x3
A	1	T
B	2	F
C	3	NaN
D	NaN	T

Filtering Joins

x1	x2
A	1
B	2

adf[adf.x1.isin(bdf.x1)]
All rows in adf that have a match in bdf.

x1	x2
C	3

adf[~adf.x1.isin(bdf.x1)]
All rows in adf that do not have a match in bdf.

Set-like Operations

ydf	zdf
x1 x2	x1 x2
A 1	B 2
B 2	C 3
C 3	D 4

pd.merge(ydf, zdf)
Rows that appear in both ydf and zdf (Intersection).

x1	x2
A	1
B	2
C	3
D	4

pd.merge(ydf, zdf, how='outer')
Rows that appear in either or both ydf and zdf (Union).

pd.merge(ydf, zdf, how='outer', indicator=True)
.query('._merge == "left_only"')
.drop(columns=['_merge'])
Rows that appear in ydf but not zdf (Setdiff)
